Acknowledgements

The assistance of many people was invaluable to the production of this report. Our thanks go to those at Human Resources and Skills Development Canada and Statistics Canada who reviewed the report and provided feedback and suggestions. A special thank you is extended to Tamara Knighton, Kathryn McMullen, Patrick Bussière and Tomaz Gluszynski for their contribution to the analysis, as well as to Danielle Baum and Rosemarie Andrews for their help in preparing the manuscript and tables for publication.

Note of appreciation

Canada owes the success of its statistical system to a long-standing partnership between Statistics Canada, the citizens of Canada, its businesses, governments and other institutions. Accurate and timely statistical information could not be produced without their continued cooperation and goodwill.

Section 1

Introduction

While doctoral graduates represent only a small proportion of the Canadian work force — 0.8% in 2006¹ – they have a significant impact on Canada’s long term economic prosperity due to their contributions to innovation and productivity growth through research and educational activities. In 2005, about 4,200 candidates earned a doctorate degree in Canada². This number is approximately one tenth the number awarded in the United States in the same year (43,400)³.

Two general concerns have been raised regarding doctorates in Canada. The first is the number of graduates the system produces. The Organization for Economic Cooperation and Development (OECD) reports that Canada lags behind other developed countries in the production of doctoral degrees. In 2007, the rate of graduation from doctoral programs (labeled “advanced research programmes” by the OECD, or ISCED level 6) was 1.1% in Canada, compared to an OECD average of 1.4%⁴. However, this figure likely overstates what may be a weakness in the Canadian higher education system, since international comparisons rely on statistics reported by a large number of countries which may not always result in data that are fully comparable. Some analysts suggest that the graduation rate has some particularly problematic characteristics⁵.

Among OECD countries, the number of doctorate graduates has increased dramatically in recent years. Auriol (2010), in an OECD project on doctorate holders,⁶ notes that 200,000 doctoral degrees were awarded in 2006 across OECD countries compared to 140,000 in 1998, representing a 40% increase in 8 years. This is in contrast to Canada, which saw 4,500 doctorate degrees awarded in 2006, compared to 4,000 in 1998, an increase of just 13%. However, numbers have increased more steeply in recent years. In 2008, for example, 5,400 doctorates degrees were awarded for an increase of 40% from 5 years earlier⁷.

Related to how many graduates are produced is the issue of where they will live and work once their education is complete. Previous research has shown that over one fifth of doctoral graduates plan to live outside of Canada upon completion of their degree (Boothby, 2008; also King, Eisl-Culkin and Desjardins, 2008). Most students planned to move to the United States, many of these in order to complete postdoctoral studies. While this represents a significant loss in human capital from the Canadian economy, the problem may be overstated since the majority of leaving graduates (55%) also indicated that they planned to return to Canada to live and work in the future. In this paper, we show that two years following graduation, 24% of leavers had returned to Canada after spending some time in the United States, while the majority still in the United States continued to have intentions of returning.

A second concern is over how doctorate holders are employed in the economy. The Canadian Council of Academies notes that Canada's level of human capital is among the highest in the world, but fewer doctorates in Canada are employed by the private sector than in many other countries. They attribute this difference to lower business demand for advanced research skills and lower private investment in advanced research compared to the United States.⁸

King, Eisl-Culkin and Desjardins (2008) also document the lower private sector employment rates of doctorate holders in Canada. They show that fewer Canadian doctoral graduates in 2005/2006 were expecting to be employed by industry than were American graduates, by about 5 percentage points. Instead, Canadian graduates were more likely to be employed by governments. While this type of comparisons to the United States is not available for this paper, we do find that most graduates are employed in a small number of industries, the largest being educational services.

The remainder of this report is organized as follows. Section two describes the data on which this report is based and discusses the advantages of using a linked data source. Section three describes the National Graduates Survey class of 2005 in terms of graduates' demographics and program characteristics. Section four examines mobility patterns, with a particular focus on graduates who move to the United States. Section five examines graduates' labour market outcomes, including employment rates, income, industry and the prevalence of overqualification. The final section provides some concluding remarks.

Section 2

The data

This report provides an opportunity to examine the outcomes of graduates more thoroughly by drawing from two different data sources that survey similar populations, but at two different points in time. The first is the Survey of Earned Doctorates (SED), which has provided annual data on doctoral graduates at the point of graduation since the 2003/2004 academic year. The second source is the National Graduates Survey (NGS), which interviews a representative sample of graduates from Canadian post-secondary education institutions two years after their graduation. The survey has been administered at four- or five-year intervals since 1982. Thus, doctoral graduates in 2005 were interviewed at the time of graduation by SED and again in 2007 by the NGS. Due to the relatively small number of doctoral graduates, both surveys are a census of doctoral graduates in Canada.⁹

Since SED is collected based on the academic year (from the beginning of July to the end of June of the following year) and the NGS data are collected for the calendar year, two waves of SED were merged to capture all graduates from the 2005 calendar year. These two classes have been described previously—2004/2005 graduates in King (2008) and 2005/2006 graduates in King, Eisl-Culkin and Desjardins (2008). The class of 2005 from the NGS has been described in Bayard and Greenlee (2009).

Non-response to the two surveys (approximately 46% for SED and 33% for the NGS) resulted in a total sample of approximately 2,500 graduates who responded to both surveys. These respondents were then weighted to represent the graduating class of 2005. In instances where the linked file did not add value to the analysis, statistics were computed with either the full SED or NGS sample in order to preserve sample size. It should be noted that SED is representative of all graduates from Canadian institutions, while the NGS and the NGS-SED linked files are representative only of graduates who remained in Canada or the United States after completion of their degrees. However, this difference did not lead to sizeable differences in key indicators between the samples (see Box 1).

Box 1: Target population of the National Graduates Survey

The target population for the 2005 NGS consisted of all graduates from a recognized public post-secondary Canadian institution who completed the requirements of an admissible program or obtained a diploma some time in 2005 and who were living in Canada or the United States at the time of the survey (with the exception of American citizens living in the United States at the time of the survey).

In-scope records are records that met all criteria in the target population as defined above. Of the 4,200 doctoral graduates in Canada in 2005, about 3,500 were considered to be in-scope graduates in 2007¹⁰.

Overall, there were no differences in the distribution of women between the two populations; 44% of graduates in 2005 were women compared to 46% in 2007. Similarly, the distribution of graduates by different fields of study was comparable, except in the social and behavioural sciences, and law where the share of graduates increased by three percentage points, from 18% to 21%.

Note: Comparisons between 2005 and 2007 were made by comparing the NGS data to data from the Postsecondary Student Information System (PSIS).

2.1 Linking the SED and the NGS

Both the SED and the NGS each have their strengths and limitations for examining doctoral graduates. For instance, since SED is conducted at the time of graduation, it contains limited information regarding employment outcomes. In fact, employment data in SED relies on the graduates' own expectations for their future employment, if they had already made plans for employment or further education. On the other hand, because SED is collected at the time of graduation, it surveys all graduates regardless of where they will be living upon completion. This is in contrast to the NGS, which, for practical purposes, includes only graduates who are living in Canada or the United States at the time of the interview. Both surveys include only recipients of a doctorate degree from Canadian institutions and not doctorate holders who immigrated to Canada. According to the 2006 Census, graduates from Canadian institutions accounted for just over half (54%) of all doctorate degree holders in Canada.

Linking the two data sources provides a unique and valuable source of data on this population beyond what is generally known from these two sources alone. The linked file creates a longitudinal data file covering doctoral graduates who graduated in 2005 and who lived in Canada or the United States in 2007. Graduates' expectations and plans at the time of graduation can be verified with data collected two years following their first interview. Furthermore, the accuracy of their expectations can be assessed, giving us a picture of the outcomes of their degrees as well as an insight into the reliability of graduates' expectations as captured by SED. Additionally, information that was collected in SED may be used to add explanatory power to the outcomes found in the NGS.

For simplicity and occasionally to meet conditions of confidentiality, the fields of study have been collapsed in order to provide larger samples. The fields were collapsed as follows:

Table 1
Comparison of detailed field of study and Classification of Instructional Programs (CIP) to collapsed list

| Collapsed list | Detailed field of study list | Classification of Instructional Programs (CIP) series and subseries |
|--|--|--|
| Life sciences | Agricultural sciences Biological sciences Health sciences | Agriculture, natural resources and conservation Biological and biomedical sciences, natural sciences All health sciences – including nutrition sciences and neurosciences |
| Engineering | Engineering | Engineering |

Note: Not all Classification of Instructional Programs (CIP) series and subseries are represented at the doctoral level.

Section 3

Profile of 2005 doctoral degree graduates two years after graduation

Two years after graduation, about 3,500 graduates from doctoral programs from the class of 2005 were living in Canada or the United States, representing 83% of the 4,200 doctorate graduates from Canadian universities in 2005.

Almost three out of ten doctoral recipients graduated in life sciences

Two fields of study accounted for nearly half of all 2005 doctoral graduates who lived in Canada or the United States in 2007: 29% graduated from life sciences programs and 19% from psychology and social sciences programs. The proportion of doctoral graduates in the four other fields of study varied between 12% and 14% (Appendix table A.1).

Six out of ten women graduated from the life sciences and psychology and social sciences

Women accounted for 46% of doctoral graduates in the class of 2005; an increase of 11 percentage points compared to their proportion in the class of 1995, which stood at 35%¹¹.

The difference between the proportion of female and male graduates was highest in engineering, where for every female (17%) there were almost five male graduates (83%), as well as in computer, mathematics and physical sciences, where the proportion of men (74%) was close to three times that of women (26%). Women made up the majority of graduates in two fields of study, namely, psychology and social sciences (64%) and education and other fields of study (56%). The proportion of women was comparable to that of men in life sciences (50%) as well as in the humanities (52% versus 48%) (Chart 1).

Chart 1
Proportion of 2005 women doctoral graduates by field of study

Source: Statistics Canada, National Graduates Survey (Class of 2005).

Moreover, about six women out of ten (59%) graduated from two fields of study, namely the life sciences (32%) and psychology and social sciences (27%). While life sciences also posted the highest share of men (27%), this proportion was lower than that of women and was followed by engineering (21%) and computer, mathematics and physical sciences (17%).

Although the median age of doctoral graduates was 33 years at the time of graduation in 2005, graduates in education and other fields of study reported the oldest median age at 42 years. These graduates were also much older at the start of their doctoral program; 36 years compared to an overall median age of 27. The relatively high age of these graduates at registration can be explained by the fact that most of them were out of the educational system during the twelve months before enrolling in their program. Indeed, seven out of ten graduates from education and the professional fields (70%) were in the labour force compared to 45% for all graduates combined (Appendix table A.5). Furthermore, they were also less likely to have taken their program full-time (56%) compared to all graduates combined (80%). Apart from education and other fields of study, there were no substantial differences in the age at the time of registration between the fields of study.

Conversely, the lowest median age at graduation was found in life sciences (31 years) and in computer, mathematics and physical sciences (30 years) (Chart 2).

Chart 2
Median age at graduation for 2005 doctoral graduates by field of study

Note: Excludes respondents for whom the age is unknown.
Source: Statistics Canada, National Graduates Survey (Class of 2005).

Chinese languages were the third largest mother tongue group

Since Canadian universities deliver their programs in either English or French and since the pursuit of a doctoral program requires very high level literacy skills, it is worth exploring the literacy profiles of doctoral graduates by examining the first language learned at home in childhood and still understood by the graduates; that is, their mother tongue.

About two-thirds of doctoral graduates (67%) reported English or French as their mother tongue (47% and 20% respectively). Another 30% had a mother tongue other than English or French; an additional 1% had learned and still understood both English and French; and finally, 2% had learned and still understood English or French along with a non-official language. After English and French, Chinese languages¹² were the third largest group, as 8% of doctoral degree holders reported a Chinese language as their mother tongue. This percentage is more than twice the proportion reported in the general Canadian population (3%).¹³ Furthermore, Chinese speakers accounted for more than one-quarter (27%) of doctoral graduates whose mother tongue was a non-official language. In addition, the vast majority of Chinese speakers (81%) as well as other non-official language speakers (87%) lived in Canada in 2007.

The proportion of graduates with a non-official language mother tongue varied greatly across fields of study. Almost two-thirds of engineering graduates (64%) as well as close to four out of ten graduates in computer, mathematics and physical sciences (37%) had a non-official language as their mother tongue. Conversely, 20% of graduates in psychology and social sciences and about 17%

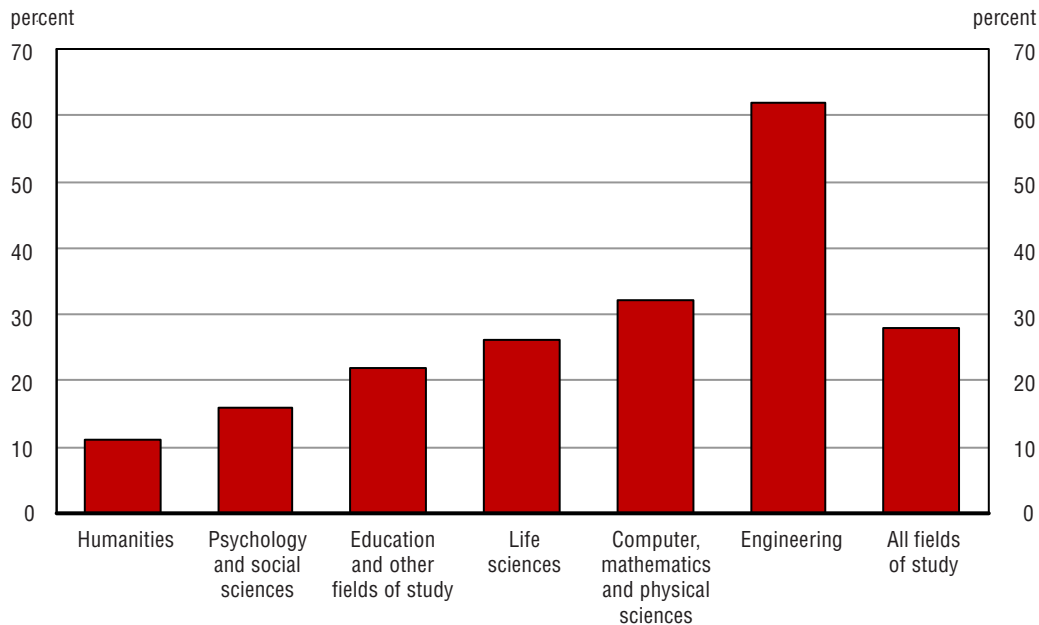

graduates in humanities reported a non-official language as their mother tongue (Appendix table A.2).

More than six out of ten engineering graduates were members of a visible minority group

Overall, 28% of doctorate graduates reported being members of a visible minority group and this proportion varied by field of study. The proportion of graduates who reported being a member of a visible minority group was higher in engineering (62%) and computer, mathematics and physical sciences (32%). On the other hand, the proportion was lower in psychology and social sciences (16%) as well as the humanities (11%, Chart 3).

Chart 3

Proportion of 2005 doctoral graduates members of a visible minority group, by field of study

Note: Only includes respondents who indicated whether or not they identified themselves as members of a visible minority ethnic or racial group.

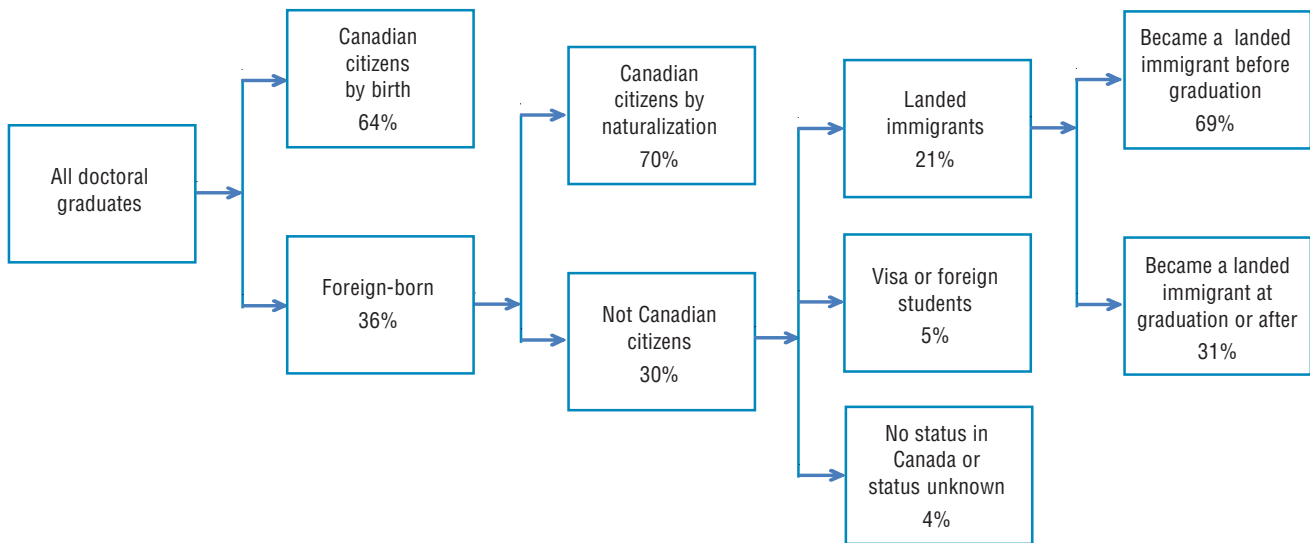

Source: Statistics Canada, National Graduates Survey (Class of 2005).

The vast majority of 2005 foreign-born doctoral graduates were naturalized or became landed immigrants by 2007

Results for engineering and computer, mathematics and physical sciences can be attributed to the fact that a high proportion of graduates in these fields of study were born outside Canada. Indeed, close to three-quarters of engineering doctoral recipients (74%) and 44% of graduates in computer, mathematics and physical sciences were born outside Canada, compared to 36% for all fields of study combined. However, the vast majority of 2005 foreign-born¹⁴ graduates who were living in Canada or the United States two years after graduation (91%) were

naturalized or became a landed immigrant by the time of the interview in 2007 (Appendix table A.3). As shown in Figure 1, more than two-thirds of immigrant graduates became landed immigrants before graduating from their doctoral program in 2005.

Figure 1
Citizenship status in 2007 of 2005 doctoral graduates

Source: Statistics Canada, National Graduates Survey (Class of 2005).

Half of doctoral graduates had a parent whose education was at least a bachelor degree

Previous studies have suggested that higher parental education results in higher education levels in children. More specifically, it showed that the type of postsecondary education pursued by young Canadians was strongly associated with parents' educational attainment. Young people whose parents had a university degree were three times more likely to pursue university studies than were those whose parents had a high school diploma or less.¹⁵

Moreover, a study of doctoral graduates in the United States showed that doctorate recipients who were American citizen were more likely than their non-citizen counterparts to report that at least one of their parents attained at least a bachelor degree.¹⁶

As shown in Chart 4, half of Canadian doctoral graduates had a parent whose highest level of education was at least a bachelor degree. There was no difference between the proportion of Canadian-born (51%) and foreign-born graduates (50%) who reported that at least one of their parents attained such a degree. In contrast, there were differences between Canadian and foreign born graduates among those whose parents did not have at least a bachelor degree. Foreign-born students were

more likely to have parents who had not pursued post-secondary education (36% versus 30% for Canadian born) whereas Canadian-born students were more likely to have parents who had completed post-secondary education below the bachelor level (18 % compared to 14% for foreign-born (Chart 4). These differences may be explained by differences in the structure of educational systems within Canada compared to other countries.

Chart 4
Highest level of parental education, 2005 Canadian and foreign-born doctoral graduates

Source: Statistics Canada, National Graduates Survey (Class of 2005).

Two graduates out of ten did not hold a master’s degree before they started their doctoral program

Not all doctoral graduates had completed a master’s degree before enrolling in their program, nor do all doctoral programs require a master’s degree for admission. In fact, according to the Survey of Earned Doctorates, about seven graduates out of ten (69%) reported that a master’s degree was a prerequisite for admission to their doctoral program.¹⁷ Graduates in the life sciences (50%) as well as those in computer, mathematics and physical sciences (57%) reported in significantly lower proportions than the overall rate that entry into their program required a master’s degree.

Similarly, these same graduates reported the lowest rates of master’s attainment at 63% and 73% respectively. Graduates in the humanities posted the highest rate of master’s attainment (95%) while the overall rate was 80%. Moreover, a similar proportion of graduates in the humanities (93%) reported that they needed a master’s degree to be admitted to their doctoral program (Appendix table A.4.1).

Typically, a median time of four months elapsed between the completion of a master’s degree and the start of the doctoral program. However, for graduates who held a master’s degree and were working during the twelve months prior to enrolling in their doctoral program, the median elapsed time between the completion of the master’s degree and the start of the doctoral studies was three years and two months (Appendix table A.4.2).

Almost four out of ten graduates were working before entering their program

About half (51%) of all 2005 doctoral graduates were in school in the year prior to enrolling in their doctoral program. Almost four out of ten graduates (38%) were working, whereas 7% were combining working and going to school (Chart 5). The highest proportions of graduates to have been in school 12 months before the start of their doctoral program were those in computer, mathematics and physical sciences (64%). They were followed by graduates in psychology and social sciences (58%), life sciences (54%) and the humanities (54%). Conversely, seven out of ten graduates in education and other fields of study were either working (60%) or combining work and school (10%) (Appendix table A.5).

Chart 5

Main activity of 2005 doctoral graduates 12 months prior enrolment in program

Note: Other activity includes: taking care of family or household responsibility, without work and looking for work and other.

Source: Statistics Canada, National Graduates Survey (Class of 2005).

More than three-quarters of graduates had firm plans at the time of graduation

Upon graduation, doctoral recipients may have firm plans to enter the labour market; to continue their research; to pursue further studies or other activities; or they may still be undecided. At the time of graduation in 2005, three-quarters of doctoral graduates had made firm plans for either employment or postdoctoral studies or training for the year following their graduation.

There was no difference in the proportion of women with definite commitments compared to male graduates (75%). The proportion of graduates with definite plans upon graduation was comparable across all fields of study, ranging from 77% to 82%, except for engineering and the humanities, both at about 65%. Furthermore, Canadian-born graduates (79%) were more likely than their foreign-born counterparts (68%) to have definite plans at the time of graduation for the following year (Chart 6).

Chart 6

Proportion of 2005 doctoral graduates with definite plans at graduation

Sources: National Graduates Survey (Class of 2005) and Survey of Earned Doctorates, 2004/2005 and 2005/2006 linked file.

More than half the graduates with firm plans (56%) expected to join the labour market upon graduation. Proportionally more women graduates (61%) than men (52%) had plans for employment, whereas about half the men (48%) were planning to pursue a postdoctoral fellowship or other training (see box 2 for a definition of postdoctoral fellowship).

In addition, there were marked differences in the type of definite plans across fields of study. Almost all graduates in education and other fields (93%) were planning to work immediately upon receiving their degree. These were followed by graduates in humanities (76%) and psychology and social sciences (70%).

Conversely, about two-thirds of life sciences graduates (69%), as well as computer, mathematics and physical sciences graduates (64%) had plans for postdoctoral studies or research when they graduated in 2005. Foreign-born and Canadian-born graduates had definite plans for postdoctoral studies in comparable proportions (at 49% and 41%, respectively) (Appendix table A.6).

Box 2: Postdoctoral positions

The Survey of Earned Doctorates defines a “postdoctoral position” or a “postdoc” as a **temporary position** primarily for gaining additional education and training in research, usually in academia, industry, or government.

In Canada, individuals who contract with a university (and sometimes a specific faculty member) to conduct academic or scholarly research that will further professional development and expand their expertise in a specialized subject are usually referred to as “Postdoctoral Fellows” or “Postdoctoral Research Associates”. They are considered trainees rather than employees by the university or research institution.

Their appointment normally occurs within five years from the completion of a doctoral degree and is time limited (often to a maximum of three years), with the possibility of renewal. The postdoctoral researcher may be funded through a salary, a stipend or sponsorship award. The amount of the fellowship typically varies between \$25,000 to \$50,000 depending on the field of research, the funding agency and the research institution.

Source: Information gathered from diverse Canadian universities’ web site.

Section 4

Graduates who moved to the United States

Canada, like most industrialized countries, is faced with an aging population and an expected shortage of skilled workers in some professions. Thus, a possible exodus of highly-educated workers or the threat of a “brain drain” not only out of the country, but also out of the labour market remains an important policy issue.

As previous studies have shown, about one fifth of the 2005 doctoral graduates (21%) intended to leave Canada upon completion of their degree and most of them (57%)¹⁸ planned to move to the United States. This section looks at the characteristics of doctoral graduates from Canadian universities who lived in the United States at the time of the National Graduates Survey (NGS) interview in 2007.

A much higher proportion of doctoral graduates lived in the United States in 2007 than was the case for graduates at the bachelor and master’s levels

Slightly more than one out of ten 2005 doctoral graduates (12%) were living in the United States in 2007. This proportion is identical to that of the doctoral graduates of the Class of 1995 who were living south of the border two years after graduation, in 1997¹⁹. Another 4% had moved to the United States after graduation but had returned to Canada by 2007 (Appendix table A.7). The 2007 “returnees” accounted for 24% of those who had moved south of the border after graduation.²⁰

In comparison, the proportions of 2005 graduates at the bachelor and the master’s levels who lived in the United States in 2007 were significantly lower at 1.3% and 2.1% respectively. These percentages are similar to those in 1997 for the graduating class of 1995 which posted proportions of 1.7% and 3.2%, respectively (Chart 7).

Chart 7

University graduates who lived in the United States two years after graduation, 1995 and 2005 graduates

Sources: Statistics Canada, National Graduates Survey (Class of 2005) and Frank, Jeff and Éric Bélair. 1999. *South of the border: Graduates from the Class of '95 Who Moved to the United States*, Statistics Canada Catalog no. 81-587-XPB. Ottawa. Statistics Canada and Human Resources Development Canada. 41 p.

About six out of ten doctoral graduates living in the United States in 2007 were Canadian citizens by birth

Of the doctoral graduates from Canadian universities who were living in the United States in 2007, about two-thirds (63%) were males and almost one-third (30%) were single. In contrast, significantly fewer graduates who lived in Canada in 2007 were men (53%) or single (22%).

Graduates who lived south of the border were also significantly younger (30 years old) than those who lived in Canada (33 years old) and almost nine out of ten (87%) were Canadian citizens, of which 59% were Canadian by birth and 28% by naturalization. These proportions are comparable to those of graduates who were living in Canada in 2007, namely 90% (65% by birth and 25% by naturalization).

Life sciences and computer, mathematics and physical sciences graduates posted the highest proportions of doctoral graduates who left Canada for the United States

A higher proportion of 2005 graduates from two fields of study were living in the United States in 2007 compared to the overall proportion who left Canada. Specifically, almost one in five graduates from the life sciences (17%) — which include agricultural sciences, biological sciences and health sciences — and a same

proportion from computer, mathematics and physical sciences (17%) were living in the United States in 2007, compared to 12% of doctoral graduates overall (Appendix tables A.7, A.8.1 and A.8.2).

As shown in Table 2 below, two detailed fields of study contributed the most to these results. About one third of graduates in biochemistry, biophysics and molecular biology (34%) were living in the United States in 2007, which is twice the proportion for all life sciences doctoral graduates. Among graduates from computer, mathematics and physical sciences, graduates in physics posted the highest proportion (28%) of graduates living south of the border.

Doctoral graduates in the health professions and related clinical sciences, on the other hand, were less likely to have left Canada, at 10% (Table 2). These rates were lowest for doctoral graduates in psychology and the social sciences as well as in education and other fields of study (each at about 6%) (Appendix tables A.8.1 and A.8.2).

Most moved for work-related reasons and a majority were attracted by the quality of research facilities or the commitment to research

About seven out of ten graduates who lived in the United States in 2007 (69%) moved for work-related reasons. Schooling or education-related reasons were reported by 20% of the movers, while one out of ten graduates moved for personal

reasons such as marriage, relationship, and family or other reasons. No significant differences in reasons for moving were observed when fields of study or gender were examined.

Chart 8
Reasons why graduates moved to the United States

Source: Statistics Canada, National Graduates Survey (Class of 2005).

Quality of the research facilities or the commitment to research was the most commonly-cited factor attracting graduates to the United States. This incentive was reported by a third of graduates, whether they moved for educational (33%) or job-related reasons (35%). Two other frequent job-related reasons for moving to the United States were a greater availability of job in a particular / specialized field or industry (27%) and better career advancement opportunities (24%). Women and men were equally attracted by these three aspects of the job.

Other common educational reasons for moving to the United States were the high academic reputation of the program or institution (29%) and the desire to study with particular colleagues or superiors (26%)²¹ (Appendix tables A.9.1 and A.9.2).

The vast majority of those who moved for educational reasons intended to take a postdoctoral position after their graduation in 2005

It is interesting to note that more than eight out of ten returnees (84%), i.e. those who moved to the United States after graduation but were living in Canada in 2007, had planned to take a postdoctoral position after their graduation in 2005. Furthermore, the vast majority (95%) of graduates living in the United States in 2007 who had moved for educational reasons had intended to take a postdoctoral position at the time of graduation in 2005²². This is in sharp contrast with graduates

who never moved to the United States after graduation. Indeed, less than half of the latter group (46%) had plans to be in a postdoctoral position following graduation (Table 3). While the National Graduates Survey does not indicate whether or not graduates who moved to the United States were in fact pursuing postdoctoral studies in 2007, these results suggest that the majority of them likely moved to take a postdoctoral position.

Table 3

Proportion of non-movers, movers and returnees who intended to take a postdoctoral position at the time of graduation

| | Proportion | Confidence limits (95%) | |

A job awaited the doctorate graduates who moved to the United States

In addition, nine out of ten graduates who moved to the United States had a job arranged to start right away upon their arrival whether they moved for job or education related reasons. Almost all movers from the fields of computer, mathematics and physical sciences (98%) and life sciences (95%) had a job waiting for them south of the border. In contrast, slightly less than 68% of those who moved to the United States from the education and other fields of study had a job upon arrival (Appendix table A.10).

Furthermore, nine out of ten doctoral graduates living in the United States (92%) were employed in the 2007 survey reference week. This proportion was comparable to the proportion of graduates who were living in Canada in 2007 and who were employed (89%). However, proportionally more male graduates living in the United States were employed compared to their counterparts who were living in Canada, while the proportions were comparable for women. Likewise, the only field of study posting a significant difference between the two groups of graduates was the life sciences: 94% of graduates living in the United States were employed compared to 87% of those living in Canada (Appendix table A.11).

Almost half of the graduates who lived in the United States in 2007 had first moved to three states: California (21%), Massachusetts (14%) and New York (12%).

Whereas only 5% of movers were permanent residents upon their arrival in the United States, this proportion had reached 12% in 2007, an increase of seven percentage points. Of the 84% who were temporary residents in 2007, about a quarter (27%) were planning to become permanent residents in the United States within the next two years (Table 4).

A majority of movers intended to return to Canada

More than eight out of ten graduates living in the United States in 2007 (83%) intended to return to Canada. This was the case for all doctoral graduates in engineering (100%) and for the great majority of those in the humanities (95%), with most (83%) of them were planning to return within five years or less (Appendix table A.12).

Section 5

Graduates' labour market outcomes

This section examines employment rates, incomes and occupations of doctoral graduates, two years after graduation. Since this information is drawn from the National Graduates Survey, it refers to graduates who were still in North America in 2007, rather than to all graduates of 2005. Those still in Canada or the United States in 2007 accounted for 83% of the graduating class of 2005.

Employment rates varied by field of study

By 2007, four graduates out of five were employed workers, with an additional five percent being self employed, and six percent being unemployed. Eight percent of graduates were out of the labour force, with the majority (about 5%) reporting that they were still in education. When these graduates were excluded, the unemployment rate increased to 7% for all graduates, though this varied considerably across fields of study. Graduates from the humanities reported an unemployment rate of 16%, which was twice as high as the next highest field, engineering at 8% (Appendix tables A.13 and A.14).

Rates of part-time employment were also quite high for certain fields of study. Excluding current students, 8% of employed graduates were in part-time employment (Appendix table A.15). The rate of part-time employment was lowest for engineering graduates at 2% and highest for humanities at 18%.

The median income for doctoral graduates in 2007, two years after graduation, was \$65,000

The median income for all graduates was \$65,000, while graduates at the 25th percentile were paid \$48,387 and those at the 75th percentile were paid \$79,000 (Chart 9).

Graduates' incomes also showed considerable variation across fields of study (Chart 9). Graduates of the life sciences had the lowest median income in 2007 at \$55,000 and also the lowest 25th percentile income at \$41,500. This is in contrast to findings from the Survey of Earned Doctorates that examined graduates expected income where in 2004/2005 and 2005/2006, graduates of the humanities expected the lowest incomes. Measured in 2007, humanities graduates had a median income of \$60,000, placing it on par with graduates from computer, mathematics, and physical sciences graduates, performing better than what they expected at the time of graduation. However, humanities graduates had the lowest income reported at the 75th percentile (\$69,000). The highest incomes were reported by graduates

of programs in education and other fields of study (\$80,000). Part of this earnings advantage may reflect prior work experience, as education doctoral graduates had the highest median age at graduation across all fields of study.

Chart 9
Income of graduates at the 25th, 50th and 75th percentiles, by field of study

Note: Excludes unpaid workers, respondents still taking education credits and those currently outside the labour force in 2007.

Source: Statistics Canada, National Graduates Survey (Class of 2005).

Box 3: How well does expected income predict actual income?

As previously mentioned, linking SED and NGS data provides an opportunity to examine the usefulness of certain measures captured in SED. Given that in SED graduates were only just entering the labour market, outcomes were approximated by asking what their expected income was if they had firm plans for employment. Lining these expectations up to actual income in 2007 (displayed here in 2005 dollars) reveals that, particularly in the lower ranges, graduates’ expectations were considerably below the median earnings reported two years later (Chart 10). Above an expected income range of \$35,000 to \$44,000, expected incomes seem to reasonably approximate actual median income, after accounting for some growth in income over the two years between SED and NGS.

Chart 10
Expected and actual income of graduates who reported an expected income in 2005 and who were employed in 2007

Note: 25th and 75th percentile income suppressed in some cases for confidentiality. Excludes those without firm plans for employment or other in 2005, as well as unpaid workers, respondents still taking education credits and those currently outside the labour force in 2007.

Sources: Statistics Canada, National Graduates Survey (Class of 2005) and Survey of Earned Doctorates, 2004/2005 and 2005/2006 linked file.

There were differences in income between men and women, immigrants and Canadian-born

Income differences were also noted between men and women and between immigrants and Canadians by birth. Across all fields of study, men were paid a median income of \$65,000 compared to \$61,000 for women. The difference was largest in education and other fields of study as well as in the life sciences, where the difference in median income was about \$8,000. While in education and other fields, the men were paid more than the women, in the life sciences it was the women who earned more than men, \$57,000 versus \$49,462. Psychology and social sciences was the only other field for which there was a significant difference, namely \$7,000. It is unclear how much of the difference may be due to more specific field of study choices within these aggregate categories.

On the other hand, the median income was comparable between the genders in engineering, in computer, mathematics and physical sciences as well as in the humanities (Appendix table A.16).

Canadian-born graduates earned a median income of \$64,000 in 2007 compared to \$60,000 for foreign-born graduates. Significant differences were also observed among humanities graduates and graduates from education and other fields of study where Canadian-born graduates earned about \$5,000 more than their foreign-born counterparts (Appendix table A.17).

Graduates with postdoctoral intentions earned less in 2007 than those without

The linked NGS-SED file adds some additional explanatory power in examining graduates' incomes. Bayard and Greenlee (2010) in their examination of graduate outcomes, note that doctoral graduates' earnings were not that different from those with a master's degree, despite a significant additional investment in learning by doctoral graduates. For men, both master's and doctoral graduates earned a median income of \$65,000, while for women; doctoral graduates earned \$5,000 more than master's graduates.²³ However, using the NGS data alone does not allow the identification of doctoral graduates who were in a postdoctoral position in 2007. Though graduates were asked to indicate if they were still in the educational system or if they were employed, postdoctoral work might best be described as somewhere in between the two.

SED asks two questions regarding postdoctoral education. The first, posed only to graduates who have already made firm plans, asks if the employment or education they will be undertaking is a postdoctoral position. The second is posed to all graduates and asks if they intended to do a postdoctoral degree. Neither is a perfect measure of graduates' activities between 2005 and 2007, but they do reveal an important distinction between graduates (Chart 11). Whereas the median income of all graduates in 2007 was \$65,000, those with postdoctoral intentions had a median income of \$54,000, while those without had a median income of \$72,000; an earning gap of \$18,000. The difference was largest in the life sciences, where graduates who intended to take a postdoctoral position earned a median income of only \$45,000 compared to the \$72,000 of graduates with no postdoctoral intentions. This illustrates that an important earning gap exists between those who planned postdoctoral work and those who intended to enter directly into the labour market. Linking these two files shows that not taking into account those in postdoctoral positions results in an underestimation of earnings of doctoral graduates.

Chart 11
Median income of graduates in 2007 by postdoctoral intentions and field of study

Note: Excludes unpaid and self employed workers, respondents still taking education credits and those outside the labour force in 2007.

Sources: Statistics Canada, National Graduates Survey (Class of 2005) and Survey of Earned Doctorates, 2004/2005 and 2005/2006 linked file.

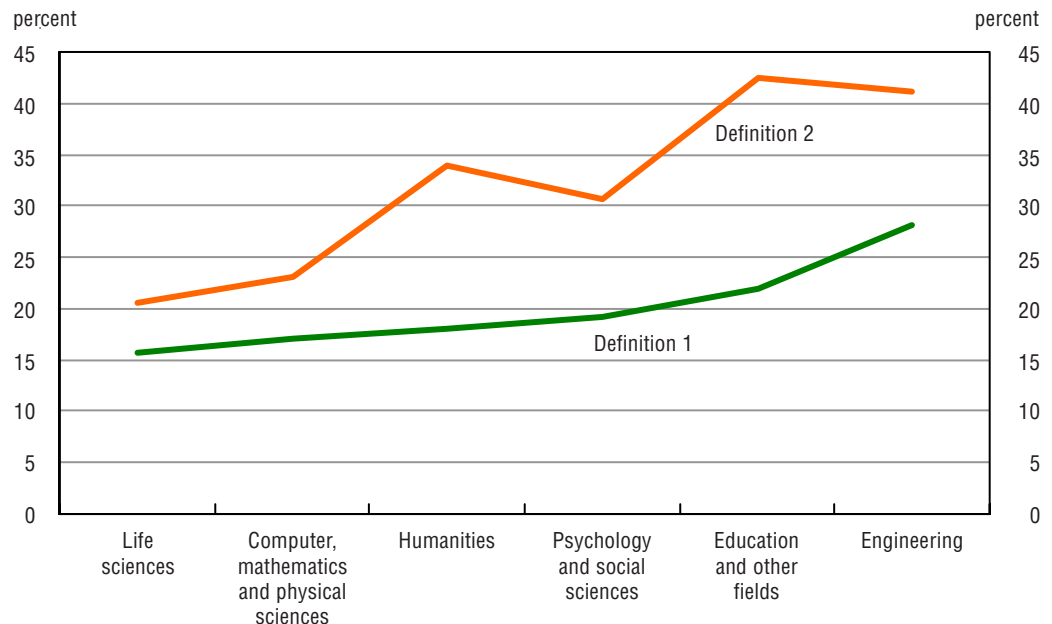

5.1 How are doctoral graduates employed?

Since doctoral education requires a large investment by the individual, often one that is matched by a similarly large investment by governments, it is important to know if these investments are worthwhile. Graduates’ income is one indicator of how a society values certain skills. Another is the match or mismatch between the amount of education required for employment and education attained. Overqualified workers have made investments in human capital that have not yet been recognised or that were not necessary for the job held in 2007. Thus, overqualification may also be thought of as the underutilization of human capital by the economy, or alternatively, as an overinvestment in certain skills by the individual and governments.

Two definitions were used to identify overqualified individuals. The first is a self-reported indicator of whether or not the graduate felt overqualified for their current position. The second was derived by matching the respondent’s educational attainment (i.e. doctorate degree) to the level of education they said was necessary to obtain the job. If less than a doctorate degree was required for their employment then they were classified as being overqualified. The results are displayed in Chart 12 below.

Chart 12

Proportion of graduates overqualified for current job, defined using 2 different definitions¹, by field of study

1. Definition 1 = subjective question, definition 2 = derived variable from job requirements to attainment.

Note: Excludes unpaid and self employed workers, respondents still taking education credits and those outside the labour force in 2007.

Source: Statistics Canada, National Graduates Survey (Class of 2005).

Overall, and for each field of study, fewer employed graduates reported being overqualified (definition one) than reported needing less than a doctorate degree to obtain their job (definition two). Approximately one in five graduates (19%) said they were overqualified, compared to 30% who reported that less than a doctoral degree was needed to obtain the job they were in.

There were notable differences across fields of study. Engineering graduates were the most likely to indicate that they were overqualified for their position (28%), while graduates from education or other fields were the most likely to report that education below a doctorate was required for obtaining their job (43%). On both definitions, life science graduates were the least likely to be overqualified (16% and 21% respectively).

The largest difference between the two definitions was in education and other fields, where an additional 21% of graduates were classified as overqualified using the second definition, and in the humanities, where an additional 16% of graduates would be considered to be overqualified.

The underutilization of graduates had an impact on earnings as well. Employed graduates who reported being overqualified for their job (definition one) had a median income that was \$5,000 lower than other graduates. Significant differences were observed between overqualified and non-overqualified graduates in psychology and social sciences (\$5,000), the humanities (\$17,000), and education and other fields of study (\$14,000). Graduates from the life

sciences, engineering and computers, mathematics and physical sciences showed no difference in median income conditional on overqualification (Appendix table A.18).

The majority of graduates were employed in educational services

A different way of examining outcomes is to look at in which industries and occupations graduates are found. Examining employment by industry reveals that graduates were clustered in a small number of industry groups and that certain industries were more closely associated with specific fields of study.

The majority of graduates (56%) were employed in educational services; the vast majority of them working in a university (87%). Employment in the educational services was highest among humanities graduates (77%) and among graduates in education and other fields (76%). It was lowest among engineering graduates (34%).

The other industries that were large employers of doctoral graduates were professional, scientific and technical services (13%), health care and social assistance (13%), public administration (7%) and manufacturing (4%). No other industry accounted for more than 2% of employed graduates (see Appendix table A.19 for the complete list).

Industry of employment varied across the fields of study (Table 5). For instance, 13% of engineering graduates were employed in manufacturing and 28% of psychology and social science graduates were employed in health care and social assistance, though overall, these two industry sectors accounted for only 17% of all doctoral graduates in the class of 2005.

Table 5
Distribution of doctoral graduates by fields of study and industry of employment

Section 6

Conclusions

This paper has highlighted several findings relevant for understanding recent doctoral graduating classes and for policy relevant research. Slightly more than a quarter of 2005 doctorate graduates (about 27%)²⁴ moved out of Canada upon completion of their degree and many still resided in the United States two years after graduation. However, 24% of those who moved to the United States after graduation in 2005 had returned to Canada by 2007, and many others were still planning to return. Previous research, (King, Eisl-Culkin and Desjardins, 2008), showed that moving to the United States is often linked to postdoctoral education. Perhaps this is why the life sciences accounted for such a large share of movers, since graduates from this field were the most likely to have plans for postdoctoral studies.

Data from the NGS show that doctoral graduates' employment outcomes vary across fields of study. Humanities graduates, for example, showed higher rates of both unemployment and part-time employment compared to graduates in other fields. However, those who were employed had a median income that was comparable to graduates from other fields of study.

Most graduates found employment in educational services, though graduates from some fields of study were found in a number of different industries. Engineering graduates were the most diverse, with significant proportions working in manufacturing, professional, scientific and technical services, and public administration as well.

The report shows that the skill set of doctorate graduates is not being fully utilized as nearly one third of graduates did not require a doctoral degree for the job they were currently doing. That being said, this finding applies to graduates only two years following graduation. It might be expected that with career progression, these doctorate holders may see the education-job skills match improve over time. This has implications for the economy and for the education choices that individuals are making.

Finally, this paper has shown that linking the SED and the NGS has increased the value of both of these surveys. The addition of information on postdoctoral education to the NGS helps to explain why there is not a larger difference observed in the incomes of master's and doctorate graduates two years after graduation. And data from the NGS has shown that graduates' expectations from SED are a poor approximation of actual outcomes as reported in the NGS, which in many cases, were better than expected. These findings are important for understanding previous research conducted with the SED and NGS and for continued improvements in education data.

Endnotes

1. Statistics Canada, 2006 Census of Population, Statistics Canada Catalogue no. 97-560-XCB2006011
2. The number of graduates reported is from the Post-secondary Student Information System (PSIS), as cited in King, Eisl-Culkin and Desjardins (2008).
3. Fiegner, Mark K. *U.S. Doctorates Awarded Rise for Sixth Year, But Growth Slower*, Arlington, National Science Foundation, Info Brief, November 2009.
4. The graduation rate is calculated by the ratio of the number of graduates in a given year divided by the population at the typical age at graduation. See Statistics Canada, 2010. *Education Indicators in Canada: An International Perspective 2010*. Statistics Canada Catalogue no. 81-604-X. Ottawa. Statistics Canada and Council of Ministers of Education.
5. Doctorate programs vary across countries in length of program, so it is not clear that Level 6 of the International Standard Classification of Education (ISCED) is in fact comparing the same level of education. Other problems with measurement persist. See for instance Adelman, Clifford. 2009. *"The Spaces Between Numbers: Getting International Data on Higher Education Straight"*. Washington, D. C., Institute for higher Education Policy, 59 p.
6. Auriol, Laudeline. 2010. *Careers of Doctorate Holders: Employment and Mobility Patterns*. Paris: OECD. 29 p. Science, Technology and Industry Working Paper Series, no. 2010/4.
7. Data from Statistics Canada, Postsecondary Student Information System (PSIS).
8. Council of Canadian Academies. 2009. *Innovation and Business Strategy: Why Canada Falls Short*. Ottawa, Council of Canadian Academies. 268p.
9. Note that the NGS excludes graduates who are no longer living in Canada or the United States in 2007
10. Out-of-scope doctoral graduates shared characteristics similar to those of 2005-2006 graduates who were planning to leave Canada upon graduation. Proportionally more out-of-scope doctorates were men, from the computer, mathematics and physical sciences and non-Canadian than was the case for the in-scope graduates. See: King, Darren, Judy Eisl-Culkin and Louise Desjardins. 2008. *Doctorate Education in Canada : Findings from the Survey of Earned Doctorates, 2005-2006*. Statistics Canada Catalogue no. 51-595MIE2008069. Ottawa, 75 p.
11. Taillon, Jacques and Mike Paju. 1999. *The Class of '95 : Report of the 1997 National Survey of 1995 Graduates*. Ottawa: Human Resources Development Canada, 19 p.
12. Chinese languages include : Mandarin, Cantonese, Hakka, Taiwanese, Chaochow (Teochow), Fukien and Shanghainese
13. Statistics Canada, 2006 Census of Population.
14. Includes visa students; however, these accounted for only 5% of all foreign-born graduates.
15. See for example: Knighton, Tamara and Sheba Mirza. 2002. "Postsecondary participation: the effects of parents' education and household income." *Education Quarterly Review*. Vol 8, no. 3: 25-32. Statistics Canada Catalogue No. 81-003-XPB2001.

17. Statistics Canada, National Graduates Survey (Class of 2005) and Survey of Earned Doctorates, 2004/2005 2005/2006 linked file.
18. King, Darren, Judy Eisl-Culkin and Louise Desjardins. 2008. *Doctoral Graduates in Canada: Findings from the Survey of Earned Doctorates, 2005/2006*. Statistics Canada Catalogue no. 51-595MIE2008069.

Ottawa. Statistics Canada and Human Resources and Social Development Canada, 75p.

19. 1997 data reported is from: Frank, Jeff and Éric Bélair. 1999. *South of the Border: Graduates from the Class of '95 who moved to the United States, an Analysis of Results from the Survey of 1995*. Statistics Canada Catalogue no.81-587-XPB. Ottawa. Statistics Canada and Human Resources Development Canada, 41 p.
20. 1995 graduates who had moved back to Canada by 1997 were not included in the *Survey of 1995 Graduates Who Moved to the United States*, conducted in 1999, but were included in the 1997 NGS. Therefore, the proportion of returnees to Canada in 1997 cannot be estimated.
21. Analysis by gender is not available due to the small sample.
22. Data from Statistics Canada, National Graduates Survey (Class of 2005) and Survey of Earned Doctorates, 2004/2005 and 2005/2006 linked file.

Culture, Tourism and the Centre for Education Statistics Research Papers Cumulative index

Statistics Canada's **Division of Culture, Tourism and the Centre for Education Statistics** develops surveys, provides statistics and conducts research and analysis relevant to current issues in its three areas of responsibility.

The **Culture Statistics Program** creates and disseminates timely and comprehensive information on the culture sector in Canada. The program manages a dozen regular census surveys and databanks to produce data that support policy decision and program management requirements. Issues include the economic impact of culture, the consumption of culture goods and services, government, personal and corporate spending on culture, the culture labour market, and international trade of culture goods and services. Analysis is also published in *Focus on Culture* (87-004-XIE, free, <http://www.statcan.ca/bsolc/english/bsolc?catno=87-004-X>).

The **Tourism Statistics Program** provides information on domestic and international tourism. The program covers the Canadian Travel Survey and the International Travel Survey. Together, these surveys shed light on the volume and characteristics of trips and travellers to, from and within Canada.

The **Centre for Education Statistics** develops and delivers a comprehensive program of pan-Canadian education statistics and analysis in order to support policy decisions and program management, and to ensure that accurate and relevant information concerning education is available to the Canadian public and to other educational stakeholders. The Centre conducts fifteen institutional and over ten household education surveys. Analysis is also published in *Education Matters* (81-004-XIE, free, <http://www.statcan.ca/bsolc/english/bsolc?catno=81-004-X>), and in the *Analytical Studies Branch research paper series* (11F0019MIE, free, <http://www.statcan.ca/bsolc/english/bsolc?catno=11F0019M>).
